## Living in a Regulated Industry

Cybersecurity standards are in a continuous state of evolution: Requirements are written and implemented, and compliance programs are maintained. Over time, events occur that provide new insights into emerging operational risks, and organizations look to new innovative technologies to help manage the risks to their businesses. This dynamic landscape creates challenges for asset owners and operators, regulators, and solutions providers, all of whom are working hard to adhere to standards while simultaneously looking ahead to a time when the standards may need to mature. This constant push and pull poses a considerable risk of stranded capital investment if the standards are always in a state of flux.

Of equal risk is the technology debt and regulatory lag that prevent effective defensive approaches if the standards have no room for innovation. The urgent need to address increasing cyber threats was the driving force behind the Biden Administration's initial efforts to protect U.S. critical infrastructure and specifically the Department of Energy's 100-day plan to enhance the cybersecurity of electric utility industrial control systems (ICSs). This effort has been further supported by the White House's National Security Memorandum on Improving Cybersecurity for Critical Infrastructure Control Systems, which specifically highlights that "deploying systems and technologies that can monitor control systems to detect malicious activity and facilitate response actions to cyber threats is central to ensuring the safe operations of these critical systems."<sup>1</sup> In March 2023, the White House also released the National Cybersecurity Strategy, which highlights "Defend Critical Infrastructure" as the number one pillar.<sup>2</sup> In Section 1.1 of that strategic plan, the need for regulated asset owners and operators to receive financial incentives was called out: "...regulators are encouraged to ensure that necessary investments in cybersecurity are incentivized through the rate-making process, tax structures, or other mechanisms." Such investments have been a significant challenge for entities throughout the years, and it is of great importance to set this expectation across the whole of government and to the organizations looking for guidance in the area of growing cybersecurity spend.

Attempts to achieve balance between compliance and security can easily be seen within many registered entities facing the difficult task of building and maintaining compliance programs for the North American Electric Reliability Corporation (NERC) Critical Infrastructure Protection (CIP) standards. As these entities consider the widespread impacts of NERC CIP on their people, processes, and technology, they have implemented various projects to meet the changing standards. As a result, they've come to realize that the truly hard work is not in the project phase but rather in the process of maintaining an effective compliance program over time.

---

<sup>1</sup> "National Security Memorandum on Improving Cybersecurity for Critical Infrastructure Control Systems," [www.whitehouse.gov/briefing-room/statements-releases/2021/07/28/national-security-memorandum-on-improving-cybersecurity-for-critical-infrastructure-control-systems/](https://www.whitehouse.gov/briefing-room/statements-releases/2021/07/28/national-security-memorandum-on-improving-cybersecurity-for-critical-infrastructure-control-systems/)

<sup>2</sup> "National Cybersecurity Strategy," [www.whitehouse.gov/wp-content/uploads/2023/03/National-Cybersecurity-Strategy-2023.pdf](https://www.whitehouse.gov/wp-content/uploads/2023/03/National-Cybersecurity-Strategy-2023.pdf)

Recent standards activity from the Federal Energy Regulatory Commission (FERC) in support of the administration’s 100-day plan and the National Cybersecurity Strategy have prompted the introduction of FERC Order 887, which directs NERC to develop standards addressing an identified gap in protection requiring internal network security monitoring. This FERC Order acknowledges the protections required under NERC CIP at the Electronic Security Perimeter (ESP) under CIP-005 and at the endpoint Bulk Electric System (BES) Cyber Asset (BCA) under CIP-007. These existing security controls provide preventive and detective controls for potentially malicious communications into and out of the ESP and controls for malicious code on a BCA. The Order further prescribes detection and response capabilities within an ESP and for communications between BCAs. In addition, FERC has also released Order 893 in response to the National Cybersecurity Strategy. That order looks to provide financial incentives to pursue voluntary advanced cybersecurity projects including operational technology (OT) network monitoring.

While the industry awaits standards development activity for internal network security monitoring (INSM) and some entities pursue voluntary OT visibility, NERC has produced guidance for entities implementing projects now through the Compliance Monitoring and Enforcement Program (CMEP) efforts. NERC has created Practice Guides to provide compliance guidance to auditors across the NERC regions on a wide variety of topics. These guides were developed with the expectation that many entities would likely pursue additional OT detection and monitoring capabilities throughout CIP-impacted facilities as a part of the 100-day plan. Whereas the ERO Enterprise CMEP Practice Guide on Network Monitoring Sensors, Centralized Collectors, and Information Sharing document<sup>3</sup> provides guidance to auditors on device categorization and areas to consider, this paper will focus on what the entity needs to consider when evaluating a technology to incorporate within its CIP program. The CMEP Practice Guide provides reference to general implementations of technical solutions for auditors to consider as they review many vendor implementations. There are numerous OT visibility solutions for an organization to review and select from, but this paper presents options available from Dragos, a leading solution provider in this space.

Regardless of where an organization is in this standards continuum, there are often multiple stakeholder views that leadership needs to consider when deciding which new technology solutions need to be integrated into a new or existing CIP program. Figure 1 represents the typical battle within most organizations.

Figure 1. Typical Perspectives About New Technology Deployments

<sup>3</sup> “ERO Enterprise CMEP Practice Guide on Network Monitoring Sensors, Centralized Collectors, and Information Sharing,” June 4, 2021, [www.nerc.com/pa/comp/guidance/CMEPPPracticeGuidesDL/CMEP%20Practice%20Guide%20-%20Network%20Monitoring%20Sensors.pdf](http://www.nerc.com/pa/comp/guidance/CMEPPPracticeGuidesDL/CMEP%20Practice%20Guide%20-%20Network%20Monitoring%20Sensors.pdf)

These perspectives and many others are at play with every technology decision across an organization's CIP programs on a daily basis. For these reasons, consider all positions when deciding on a technology solution that will be integrated into a CIP program.

This paper examines one of the more common technologies being pursued currently across the CIP universe of electric utilities: OT network visibility and detection solutions.

*Note: NERC uses specific terminology that has defined meaning in the context of its protocols and rules. Throughout this paper we have chosen to preserve NERC's terminology and associated capitalization. For more information, see NERC's Glossary.<sup>4</sup>*

## Considering a New Solution: The CIP Gauntlet

Figure 2 presents some of the reasons why organizations might pursue technical solutions. Regardless of the reason, however, there is an evolutionary process that an organization goes through when evaluating a CIP solution. Here are the typical stages:

1. Admit you have a problem.
2. Determine whether the solution creates more problems than it solves.
3. Decide how the solution can help you manage the existing problems.
4. Discern whether the solution can help you address future problems.
5. Determine whether the solution provider understands that you have a problem.

Figure 2. Process of Pursuing Technologies Integrated into a CIP Program Solution

<sup>4</sup> "Glossary of Terms Used in NERC Reliability Standards," [www.nerc.com/pa/Stand/Glossary of Terms/Glossary\\_of\\_Terms.pdf](http://www.nerc.com/pa/Stand/Glossary%20of%20Terms/Glossary_of_Terms.pdf)

As we walk through these five stages of CIP evolution, we also look at the Dragos Platform as one of the leading products in the ICS network visibility and detection space. The platform is likely on the short list of product offerings to review and consider for entities managing NERC CIP programs. Specifically, we look at the Dragos Platform V2.2 and the on-premises deployment approach, including the Dragos SiteStore and distributed Dragos Sensors.

## Admitting There Is a Problem Is the Hardest Part

Building programs to achieve compliance is the easiest task on an entity's to-do list, but such programs typically require the greatest capital investment. During this project phase, the organization will determine what the requirement language means, select an approach to achieve the intent of the interpreted requirement language, develop policies and procedures on how to operationalize the program, and then implement the technical solutions and procedural controls. As CIP history has rolled forward, entities have learned that they may have achieved initial compliance, but it was with high levels of reliance on one or more of the following:

- Spreadsheets
- Procedural controls
- Physical controls
- Calendar alerts for periodic performance of actions
- Work management ticketing systems for performance reminders
- Scripts to copy logs for retention
- Events that highlighted gaps in a CIP program
- Large amounts of human heroics

Recognizing the need for an effective program that goes beyond initial compliance is the first step.

Understanding the problem space here can be a challenge and might be counterintuitive—the stronger your program and your solutions, the more violations you will discover. If you do not know what a compliance violation is and do not run an active program, then you will likely not find any violations until an audit team does. Similarly, if you are not actively monitoring your operational networks and implementing detective controls, then you will likely not find any threats until a potential system-impacting event occurs. NERC CIP eventually brings entities to the following realization: “We either need to run an effective CIP program now or do it later and face a fine. Either way, we need to get there.”

As organizations recognize the problems within their CIP programs and consider pursuing technical solutions to integrate into their CIP programs, they progress to the next stage: “Will this solution make my problems worse?”

## Will the Solution Help?

When considering a technical solution to enhance a NERC CIP program, assess how the solution will fit within that program. The solution must first meet the compliance program's requirements. To highlight this review process, let's look at the Dragos Platform device's SiteStore and Sensors.

Ideally, although all the standards integrate with each other within an effective CIP program, there are some standards that pertain to devices more specifically.<sup>5</sup> In evaluating the Dragos Platform Sensors and SiteStore components, this paper focuses on the compliance requirements of the following standards specifically:

- CIP-007, including some elements of CIP-004
- CIP-009
- CIP-010
- CIP-011

When evaluating a particular solution to be utilized in a CIP program, individual components will pass through a series of decision gates. Some of those decision gates that apply to OT network visibility tools include:

- Why is it subject to CIP?
  - What does it do? (In the case of OT network visibility tools, they are typically used to satisfy specific CIP requirements across numerous standards.)
  - Where is it? (In the case of OT network visibility tools, they typically have sensors or collectors within CIP-identified Electronic Security Perimeter [ESP] network segments and aggregators outside of the CIP ESP network segments.)
  - What data does it contain? (In the case of OT network visibility tools, they typically have sensitive system information, logs, and event data that need to be protected.)
- Is it a Cyber Asset?<sup>6</sup>
  - What are the programmable electronic devices, including the hardware, software, and data in those devices? (In the case of the Dragos Platform, Dragos Sensor and SiteStore certainly satisfy the Cyber Asset definition.)
- Is it a Bulk Electric System (BES) Cyber Asset?
  - A BES Cyber Asset is one that, if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or nonoperation, adversely impact one or more facilities, systems, or pieces of equipment, which, if destroyed, degraded, or otherwise rendered unavailable when needed, would affect the reliable operation of the BES. (In the case of the Dragos Platform, there are no associated real-time reliability tasks being performed by the components that would affect the BES within 15 minutes. An entity needs to evaluate its CIP-002–documented approach for misuse considerations with each Cyber Asset to ensure it has established “misuse” consideration boundaries.)

<sup>5</sup> “Standards,” [www.nerc.com/pa/Stand/Pages/default.aspx](http://www.nerc.com/pa/Stand/Pages/default.aspx)

<sup>6</sup> “Glossary of Terms Used in NERC Reliability Standards,” [www.nerc.com/pa/Stand/Glossary of Terms/Glossary\\_of\\_Terms.pdf](http://www.nerc.com/pa/Stand/Glossary of Terms/Glossary_of_Terms.pdf)

- Where is it?
  - What is the Impact Rating<sup>7</sup> of the facility where the solution is implemented? (In the case of the Dragos Platform, the solution will likely be found in high-impact control centers, as well as medium-impact control centers, generating stations, and transmission substations. The solution elements also may be found in low-impact control centers, generating stations, and transmission substations, but the CIP requirements for these low-impact facilities are not as significant or direct as with the high- and medium-impact facilities.)
- Is it inside an ESP?
  - If a Cyber Asset is connected using a routable protocol within or on an ESP, then that device should be treated as a Protected Cyber Asset (PCA) within the same impact rating as the ESP it is in. (In the case of the Dragos Platform, the sensors within the ESP would be treated as high or medium PCAs, depending on the impact rating of the facility.)
- What does it do for CIP?
  - Cyber Assets that perform electronic access control or electronic access monitoring of the ESP(s) or BES Cyber Systems are treated as Electronic Access Control or Monitoring Systems (EACMS). (In the case of the Dragos Platform, the SiteStore receiving electronic access monitoring of BES Cyber Systems would commonly be treated as an EACMS.)

With an understanding of why the various elements are subject to CIP—and specifically how they are subject to CIP based on the various Standards Requirements applicability tables<sup>8</sup>—an entity can now begin to identify which requirements must be satisfied by a particular solution. Let’s look at the requirements that commonly apply to the Dragos Platform and the capabilities that exist to integrate the solution into an entity’s CIP program.

## Does the System Purchased for Compliance Comply?

Prior to highlighting each Standard and the applicable Requirements, it is important to understand that no solution is inherently “compliant.” The Dragos Platform and associated Dragos Sensors and SiteStore can be configured to satisfy compliance requirements, which is an important differentiator because not all solutions on the market are configurable nor do all solutions have the capabilities necessary to comply. To demonstrate ongoing compliance, your organization needs to provide performance evidence that it has implemented a program to sustain compliance with the requirements over the life of the assets. This isn’t something you buy—it is something you do. This paper covers the standards with specific applicability to Dragos Platform assets.

## CIP-007

CIP-007 is the Systems Security Management Standard and provides the requirements that need to be satisfied by applicable systems within a CIP program. There are five parent-level requirements and more than 20 subrequirements within CIP-007. Table 1 shows the applicable requirements and associated impact rating specifics.

**Table 1. CIP-007 Applicable Requirements and Associated Impact Ratings**

| Requirement                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                  | Dragos Sensor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Dragos SiteStore                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>R1.1, 1.2</b>                                              | Enable only required logical network-accessible ports, prevent unauthorized access to physical ports.                                                                                                                                                                                                                                                                                                        | The Dragos Sensor and SiteStore systems have been hardened and have limited network-accessible logic ports required for operations through application restrictions, local iptables fw rule set, and interface configurations that limit the network-accessible ports to only those required for communications with the endpoints and SiteStore. The V2.2 platform instance has moved toward an appliance-class solution, which significantly eases the administration and many of the compliance burdens present in a traditional managed server solution. In addition, the sensor device can be configured to disable unused physical ports through logical configurations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | The SiteStore is typically categorized as an EACMS based on the logical implementation and is not applicable to R1.2. The system hardening approach and limitation of operationally required logical network-accessible ports approach is performed in a similar manner as the Dragos Sensor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>R2.1, 2.2, 2.3, 2.4</b>                                    | Patch sources for CIP-010 baseline-related items must be identified and a patch management process for tracking, evaluating, and installing applicable security-related patches on a 35-day calendar cycle shall be implemented. Security patches will be evaluated for applicability and then, in the next 35-day cycle, they will be applied, mitigated, or added to an existing mitigation plan.          | For both the Dragos Sensor devices and the SiteStore devices, CIP entities would list Dragos as their patch source and would verify within a rolling 35-day calendar cycle if any applicable security patches have been released. Security-related patches do not include bug fixes, feature updates, or knowledge packs and would only apply to specific security-related patches. If an applicable security-related patch was available, then the entity would need to identify that fact during its first patch assessment 35-day window and move the applicable patch into the next 35-day window to apply, mitigate, or update an existing mitigation plan. Maintaining access to ongoing security-related patches requires an active Dragos support agreement. In the new V2.2 platform, the updating of patches and knowledge packs has become significantly easier through the web management interface (see Figure 4). Additionally, supported platform extensions have been added as part of the platform and therefore no longer need to be identified as intentionally installed software outside of the core product. This is beneficial because it eliminates the need for multiple patch sources and patch tracking cycles across multiple vendors. | The SiteStore approach is the same as the Dragos Sensor approach.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>R3.1, 3.2, 3.3</b>                                         | Deploy methods to deter, detect, or prevent malicious code and implement a process for signature or pattern updates.                                                                                                                                                                                                                                                                                         | For both the Dragos Sensor devices and the SiteStore devices, Dragos has implemented controls to prevent malicious code through system hardening. On the V2.2 platform, Dragos customers largely treat the system similar to the way they'd handle network infrastructure equipment with hardened firmware that prevents installation of software or introduction of malicious code, thereby having its own inherent method of deterring malicious code. Previous versions of the platform included Clam AV to satisfy this requirement uniquely. Although this is no longer a recommended approach on the appliance-based V2.2, if customers require it, they can work with Dragos support and engineering to discuss custom configurations on V2.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | The SiteStore approach is the same as the Dragos Sensor approach.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>R4.1, 4.1.1, 4.1.2, 4.1.3, 4.2, 4.2.1, 4.2.2, 4.3, 4.4</b> | Perform event logging, including successful logins, failed logins, failed access attempts, and detected malicious code. Alerts must be generated for event logging failure and detected malicious code. Logged events shall be retained for 90 days, and for high-impact facilities, a summary of the logs will be reviewed every 15 days.                                                                   | The Dragos Sensor and SiteStore can generate logs for successful logins, failed logins, failed access attempts, and detected malicious code, sending those to the SiteStore for log retention and alerting if malicious code is detected. The capability to alert on failure of logging can be established based on communication loss to the SiteStore. Log retention is a requirement satisfied on the SiteStore storage configuration. Log review is a procedural task within a CIP program. In addition, the Dragos Sensor and SiteStore can be configured to send logs to a variety of other third-party SIEM solutions or ingest logs from other solutions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | The unique requirement applicability of an alert that needs to be generated for a failure in event logging that would be visible in the alerting system creates an odd circular requirement for an alerting system. This requirement would typically be satisfied by the observable loss of the alerting system, which in this case is the SiteStore, where the logging and alerts of logging failure would appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>R5.1, 5.2, 5.3, 5.4, 5.5, 5.5.1, 5.5.2, 5.6, 5.7</b>       | Enforce interactive user authentication, enforce password complexity and length, require password changes every 15 months, and limit unsuccessful authentication attempts or alert on an exceeded threshold of unsuccessful attempts. All default and shared accounts must be inventoried. Identify individuals who have authorized access to those accounts and change the known default account passwords. | For interactive user accounts, the Dragos Sensor and SiteStore can support local accounts and connectivity to directory-based systems where the R5 requirements can be easily achieved (see Figure 3). For default user accounts, any problems are typically resolved during initial deployment with the Dragos service team. During a Dragos Sensor or SiteStore deployment, the default accounts can be inventoried and passwords can be altered through a series of scripts and commands that the deployment team can walk personnel through. The entity can then establish new passwords and determine who will have access to them. Outside of local authentication capabilities, the V2.2 platform allows for integration into Active Directory, LDAP, and OpenID Connect-compatible authentication providers. This is a significant benefit because it allows many entities to incorporate the Dragos solutions in their traditional account provisioning/deprovisioning workflows.                                                                                                                                                                                                                                                                         | Although everything that was referenced for the Dragos Sensor applies to the SiteStore, the CIP-004 Requirement 5.4 includes a requirement for default password changes based on a triggering event. Because individuals with access to the default account passwords leave the organization voluntarily or through termination, the entity must change the passwords within 30 days for EACMS devices associated with Control Centers. Although the SiteStore is typically categorized as an EACMS, and a sensor may be a PCA due to its location in the ESP, it would be wise to treat the sensor to the same change requirement due to its role in the EACMS monitoring function. The challenge for entities is maintaining the change requirements over the life of the asset and requires access to Dragos support for response within the appropriate timeframe. |

Figure 4. System Upgrades and Knowledge Pack Management

CIP-009

CIP-009 is the standard that addresses recovery plans for BES Cyber Systems and contains several requirements that apply to the Dragos SiteStore as an EACMS but not to the Dragos Sensors as a PCA. As mentioned earlier, however, it would be wise to configure the Sensors to comply with the applicable EACMS requirements, due to its role in the monitoring function.

Much of CIP-009 Requirement 1 is looking for recovery plans, identification of individual roles and responsibilities, processes to back up information required to recover the function, verification of the backups, and methods to preserve forensics data from the device if there has been an identified Cyber Security Incident. In the case of the Dragos Platform assets, entities will need to develop not only the processes used to back up the system configuration from the Dragos Sensor and the SiteStore, but also a process to test the recovery of the system build and configuration and methods to perform a backup of all system data for use in analysis after the fact but before a system is recovered. Dragos provides a series of scripts to perform these backup and recovery tasks, as well as platform backup capabilities to export the configurations in use (see Figure 5).

The other CIP-009 requirements are more programmatic, with associated performance periods and evidence retention demonstrating testing, validation, and plan reviews.

Figure 5. Backup (Export) Configuration on the Dragos Platform

## CIP-010

CIP-010 is the standard that addresses Configuration Change Management and Vulnerability Assessments for BES Cyber Systems and other applicable systems. The complicated standard has some unique considerations with regard to its applicability to the Dragos Platform. Table 2 presents the specifics.

**Table 2. CIP-010 Applicable Requirements and Associated Impact Rating Specifics**

| Requirement                                    | Description                                                                                                                                                                                                                                                                                    | Dragos Sensor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Dragos SiteStore                                                  |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>R1.1, 1.1.1, 1.1.2, 1.1.3, 1.1.4, 1.1.5</b> | Document the baseline configuration that includes the operating system, intentionally installed software, custom software, logical network-accessible ports, and security patches applied.                                                                                                     | The Dragos Sensor and SiteStore operating system in the V2.2 platform is named DragOS. Consider the OS as a customized Linux implementation created by Dragos containing numerous packages, containers, scripting language processors, custom applications, associated security patches, and configuration files resulting in the network-accessible logical network ports. During system deployment, the Dragos support team utilizes a series of system setup guides to generate an as-built system baseline. | The SiteStore approach is the same as the Dragos Sensor approach. |
| <b>R1.2, 1.3, 1.4, 1.4.1, 1.4.2, 1.4.3</b>     | The remaining subrequirements within Requirement 1 are programmatic in nature, pertaining to authorization of changes, updating baseline, ensuring security controls have not been impacted, and documenting the verifications. R1.5 and 1.6 do not apply.                                     | Programmatic inclusion of the asset is inherently a part of the entity process over the life of the Dragos Sensor and SiteStore. NERC CIP-specific compliance considerations specific to a customer deployment may be necessary. These specific security control approvals will need to be coordinated and documented for appropriate compliance evidence during system updates.                                                                                                                                | The SiteStore approach is the same as the Dragos Sensor approach. |
| <b>R2.1</b>                                    | The programmatic process of monitoring for changes to the baseline is covered here.                                                                                                                                                                                                            | Programmatic inclusion of the asset is an inherent part of the entity process over the life of the Dragos Sensor and SiteStore.                                                                                                                                                                                                                                                                                                                                                                                 | The SiteStore approach is the same as the Dragos Sensor approach. |
| <b>R3.1, 3.3, 3.4</b>                          | Every 15 months, perform a paper or active vulnerability assessment prior to adding a new, applicable Cyber Asset. For Control Center-associated systems, perform an active vulnerability assessment. For all assessments, document the results and remediation plans. R3.2 is not applicable. | Programmatic inclusion of the asset is an inherent part of the entity process over the life of the Dragos Sensor and SiteStore. The Dragos product team works with customers on contributing details necessary for developing remediation or mitigation plans.                                                                                                                                                                                                                                                  | The SiteStore approach is the same as the Dragos Sensor approach. |
| <b>R4</b>                                      | Programmatic protection requirements cover Transient Cyber Assets (TCA) and Removable Media (RM).                                                                                                                                                                                              | Programmatic inclusion of the asset is an inherent part of the entity process for the use of TCAs or RM with the Sensor or SiteStore assets over the life of the Dragos Platform.                                                                                                                                                                                                                                                                                                                               | The SiteStore approach is the same as the Dragos Sensor approach. |

## CIP-011

CIP-011 is the standard that addresses information protection and is the last standard for which this paper defines the unique applicability considerations to the Dragos Platform. The first requirement in CIP-011 addresses the programmatic need for a method to identify BES Cyber System Information (BES CSI) that includes information about the BES Cyber System that could be used to gain unauthorized access or pose a security threat to the BES Cyber System. Almost more important is determining what is *not* BES CSI, meaning the information does not include individual pieces of information that could be used to gain unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual IP addresses without context, ESP names, or policy statements.

Considering these definitions and additional information about BES CSI, it is safe to assume that the contextual logs, alerts, indicators, and security event-related information from BES Cyber Systems that are stored and processed in the sensors and SiteStore would be treated as BES CSI. Therefore, additional access control requirements of CIP-004 apply to users of the Dragos Platform in relation to granting access, reviewing access records, and removing access in line with the overall CIP-004 program. CIP-004-7 Requirement 6 addresses new approaches to perform access management for BES Cyber System Information, including new requirement language for BCSI located in cloud storage environments.

In addition, the Dragos Sensor and SiteStore are subject to CIP-011 Requirement 2 for data destruction or sanitization prior to disposal or reuse.

The standards review element of product selection is one of the more important steps in evaluating a solution for appropriate fit within a CIP-regulated environment. The Dragos Platform, consisting of associated sensors and SiteStore devices, is absolutely capable of meeting the compliance requirements during initial build and implementation with routine deployment support from Dragos customer support. Maintaining a CIP-compliant solution is achievable with the Dragos Platform. Compliance performance always will rely heavily on entity programs, processes, and for some requirements, ongoing support from Dragos.

## **Does the Solution Do What It Was Purchased to Do?**

When looking for solutions and tools to aid in an entity's performance of CIP obligations, be sure to put them through the CIP approval gauntlet covered in this paper. If a solution does not meet the compliance requirements, regardless of how awesome the security team thinks it is, it will create self-reported violations, or worse, lead to the discovery of a possible violation during an audit. You do not want to put your organization in a situation requiring programmatic changes, mitigation plans, reconfiguration of the associated solution, or a replacement of the selected solution. After a solution has passed the gauntlet, the entity can start implementing it to solve the problems it was selected to address. In the case of the Dragos Platform, any of the following standards or initiatives may have been the driving force behind the product selection:

- CIP-002: BES Cyber Asset identification and inventory
- CIP-005: Malicious communications detection
- CIP-007: Security event monitoring and alerting
- CIP-010: Change management of BES Cyber Assets, especially nontraditional OT devices
- The coming Internal Network Security Monitoring Requirements or Advanced Cybersecurity Projects captured under FERC Order 893

This section covers solution feature sets that specifically align with performance of these requirements.

CIP-002

CIP-002 is the standard that sets the scope of an entity's CIP universe. All assets the organization owns and operates are evaluated against the CIP impact rating criteria to determine whether those assets should be considered high, medium, or low impact. Then the difficult efforts begin to identify the Cyber Assets and BES Cyber Assets used by, located at, or associated with the facilities.

In some of these facilities, obtaining an accurate inventory can be a significant challenge requiring months of effort. Leveraging a system like the Dragos Platform, which can be implemented with OT environment visibility and passively see device communications, over time will almost certainly assist an entity in its efforts to identify and inventory device types present in its facilities.

The asset maps (shown in Figures 6a and 6b) provided in the platform offer many options, including:

- Displaying conversations
- Baselining environments and monitoring changes to baselines of communications
- Rolling back views with a time slider, enabling determination of what the environment looked like at a previous point in time (helpful in demonstrating that the architecture and assets were consistent throughout an audit period and identifying when a change or security-related event of interest may have occurred)

| ASSET INVENTORY                           |                            | ZONES                              |                          |
|-------------------------------------------|----------------------------|------------------------------------|--------------------------|
| <input type="text" value="Search Zones"/> |                            | <button>+ NEW ZONE</button>        | <button>REFRESH</button> |
|                                           |                            | <button>EDIT PARENT ZONES</button> |                          |
|                                           |                            |                                    |                          |
| Corp                                      |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| CDMZ                                      | DMZ                        | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| IDMZ                                      | DMZ                        | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Substation North                          | Distribution               | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Substation South                          | Distribution               | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Substation East                           | Low Impact (Transmission)  | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Substation West                           | Low Impact (Transmission)  | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Control Center                            | Medium Impact (Generation) | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Plant 1 Unit 1                            | Medium Impact (Generation) | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Plant 1 Unit 2                            | Medium Impact (Generation) | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Primary Control Center                    | High Impact (Transmission) | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Backup Control Center                     | High Impact (Transmission) | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Vendor Network                            |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| DMZ                                       |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Distribution                              |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Low Impact (Transmission)                 |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| Medium Impact (Generation)                |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |
| High Impact (Transmission)                |                            | <a href="#">EDIT</a>               | <a href="#">DELETE</a>   |

Figure 6a. Asset Map List Showing Zones on the Dragos Platform

Figure 6b. Visual Asset Map Showing Zones on the Dragos Platform

These types of capabilities can be expanded by creative compliance teams to track when a Transient Cyber Asset was added to an environment and demonstrate that it only lived in that space for less than 30 consecutive days (as defined in the NERC Glossary of Terms).<sup>9</sup> They can also be helpful in demonstrating negative conditions such as the absence of “shared BES Cyber Systems” communicating with each other across segmented generation units to achieve impact rating reductions under CIP-002 Attachment 1, Criteria 2.1.

Figure 7. Asset Attributes and Details on the Dragos Platform

Leveraging the asset inventory and the device details (see Figure 7) can be of great benefit to compliance teams as they track all the assets subject to CIP and the various applicability designations. Having a view-only capability to the Dragos Platform can allow a compliance analyst to review static inventory lists against those that are actively discovered within an environment and information about the communications observed, including the devices involved. This review could be important in incident identification, ESP rule establishment, classifying asset communications that perform External Routable Connectivity, and appropriate remote access approaches.

Although CIP-002 consists primarily of requirements that direct entities to perform applicability reviews and categorization efforts, it also has within it the inherent need to identify the Cyber Assets and the unique applicability of those devices. This identification may have previously been performed with spreadsheets, manual wire-tracing tasks, system build documentation reviews, and other tools at each site, but this task is required to be reviewed every 15 months. Due to the burden of effort, it is easy to miss a new asset addition or removal.

As tools like the Dragos Platform are utilized by entities for compliance with requirements in other standards, security and compliance teams should consider it for additional areas of inclusion across an entity’s broader program.

<sup>9</sup> “Glossary of Terms Used in NERC Reliability Standards,” [www.nerc.com/pa/Stand/Glossary%20of%20Terms/Glossary\\_of\\_Terms.pdf](http://www.nerc.com/pa/Stand/Glossary%20of%20Terms/Glossary_of_Terms.pdf)

## CIP-005

CIP-005 is a standard with specific focus on Electronic Security Perimeters (ESPs) that, through a series of preventive and detective controls requirements, are designed to be the first line of defense for an entity. CIP-005 is also one of the CIP Standards where a solution like the Dragos Platform directly addresses many of the requirements.

Within CIP-005, the most common requirement that would send entities out to evaluate solutions like the Dragos Platform is CIP-005 R1.5. This requirement applies at high- and medium-impact rated Control Centers and directs entities to implement detective controls for known or suspected malicious communications for inbound and outbound communications. Historically, entities have pointed at their firewalls and asserted that the rulesets would appropriately block malicious communications. Over time, however, questions such as, “Does that mean every communication that is blocked is malicious?” and “Does that mean everything that is allowed is non-malicious?” have become frequent. Adversary attacks have shown that attackers commonly utilize the existing tools and technologies within a target environment to perform adversary actions. In this way, an adversary may use approved communications methods to pass through a perimeter device and then perform many actions within a perimeter that will go undetected. In an effort to detect the adversary attack approaches, entities moved toward deployments of intrusion detection systems within and outside of ESP environments because they needed to satisfy the requirement language to detect ingress and egress of malicious communications. Although these approaches provide great detections for traditional IT attack activity, they do not typically render useful insights into malicious communications within OT environments.

As companies such as Dragos developed the OT visibility market, organizations have adopted these solutions within OT environments because they provide ICS-aware detections. Demonstrating sensor placement with visibility to ingress and egress communications is necessary to demonstrate compliance with CIP-005 R1.5. As shown in Figure 8, the Dragos Platform architecture places sensors within the ESP and outside the ESP to demonstrate appropriate compliance with the R1.5 language.

Figure 8. Dragos Platform Deployment Diagram

There are a few other CIP-005 requirements worth mentioning where the Dragos Platform may have some worthy capabilities in a CIP compliance program:

- **CIP-005 R1.2: All External Routable Connectivity must be through an identified Electronic Access Point (EAP).** The Dragos Platform can help entities identify any communications that could be occurring externally (and not going through an identified EAP) through the use of the asset map and the communications analysis capabilities.
- **CIP-005 R2.4: Determine active vendor remote access sessions (interactive or system to system).** The Dragos Platform will certainly capture the communications that occur and can be used to identify which connections exist. Entities can also implement additional displays and dashboards to indicate when an interactive session or potentially baseline routine system-to-system remote access is established to highlight when an event of interest occurs. (See Figures 9, 10, and 11.)

Although CIP-005 provides the initial electronic perimeter defense requirements, additional CIP Standards exist to ensure additional security protections are in place in the event the perimeter is compromised.

Figure 9. Dragos Platform Threat Detection Dashboard

Figure 10. Example Notification of a Malicious Binary Indicator

Figure 11. Example Notification of Suspicious Network Behavior

CIP-007

CIP-007 is the Systems Security Management Standard that focuses on the hardening of assets through a series of procedural and technical controls. CIP-007 addresses broad topics, such as restricting accessible ports and services on an applicable Cyber Asset, patching, malicious code detection, and account management. The requirements directly applicable to solutions like the Dragos Platform are found in CIP-007 R4: Security Event Monitoring.

CIP-007 R4.1 provides specific guidance about what types of events must be logged on an applicable Cyber Asset:

- R4.1.1 addresses detected successful login attempts (see Figure 12).
- R4.1.2 deals with detected failed access attempts and failed login attempts (see Figure 13).
- R4.1.3 addresses detected malicious code.

Because the capability to perform logging varies and may be limited on some devices within OT environments, there are certainly some limitations on devices to perform each of these actions. These limitations are recognized in the requirement language when it states that these items need to be logged per system and per asset capability. So, where capable, these events need to be logged and the logs retained for 90 days. In addition, for Control Center environments, a summary or sample set of the logs must be reviewed every 15 days to identify potential Cyber Security Incidents.

To satisfy these logging requirements, entities have pursued solutions capable of collecting and storing these various asset logs. For Windows system logs and syslog-capable systems, this is an area where the Dragos solution helps. The platform can be configured to collect various system log file formats and can indirectly collect log data from existing SIEM solutions. All of this can then be forwarded to the SiteStore for retention and routine review as required within CIP-007 R4.

Figure 12. Remote User Login Detection Summary

Figure 13. Failed Login Attempt Detection Logging

In addition to the CIP-007 R4 logging requirements, there are also requirements to generate alerts for security events within CIP-007 R4.2:

- R4.2.1 addresses how to generate alerts for detected malicious code.
- R4.2.2 focuses on generating alerts for detected failure of event logging.

An additional alerting requirement appears under CIP-007 R5.7 for generation of alerts after a threshold of unsuccessful authentication attempts.

The manner in which these system alerts can be achieved varies by asset type. For example, a network infrastructure switch or a substation digital protection relay cannot typically detect malicious code and, thus, would not be capable of generating an alert for detected malicious code. Therefore, a solution that can ingest direct alerts as well as offer the customization capabilities to identify alert conditions within log files is ideal.

In the case of detected malicious code, some AV solutions generate an event in a system security log if a detection is triggered, whereas others only generate a detection notification within the application. In these cases, the data can be pulled and pushed to solutions like Dragos through the use of scripts and other approaches. Once the data has been pushed to the SiteStore, custom dashboards and alerts can be created. Two are shown in Figure 14 on the next page.

The requirement to generate alerts for failure of logging can be tricky because although events may be generated to indicate logging failure, in many systems there is no such alarming of log failure.

Too often, entities configure dashboard screens that highlight some of the wonderful features of a tool: top talkers, top protocols, bandwidth consumption, link status, peak traffic times, and the like. Unfortunately, none of this information helps demonstrate compliance with CIP-007 R4. CIP-specific dashboards and reports that demonstrate the performance of the required logging and alerting are specifically helpful in demonstrating and ensuring compliance.

In addition to the R4 requirements, CIP-007 R1 also requires entities to configure applicable Cyber Assets in a manner that ensures only the necessary ports and services are enabled. As these network-accessible logical ports are identified and configured, the communications captured and displayed within the Asset Explorer can be used as a secondary control to show that the applicable Cyber Assets are operating as intended over time.

Figure 14. Dragos Platform Summary Dashboards of Ingested Data

CIP-010

CIP-010 is the Configuration Change Management and Vulnerability Assessments Standard. If you consider CIP-007 as the system hardening standard, then CIP-010 exists to ensure the system remains in that hardened configuration, to ensure that changes do not affect security controls, and to provide additional requirements to identify any vulnerabilities that may exist. It also ensures TCAs and RMs are used in a secure manner. CIP-010 R1 and R2 consist of programmatic and procedural elements that are required to ensure that system baselines exist and that changes to a system are verified, tested, authorized, and updated within an appropriate period of time. The performance of these tasks can be exceptionally manual, especially with ICS devices. Utilizing elements of the Dragos Platform to develop baselines of specific ICS devices (see Figure 15) and integrating these detective controls into the larger CIP configuration change management program can help demonstrate compliance with these tasks on nontraditional devices.

Baseline Settings

General Settings

The Baseline feature performs detections on asset deviations that include non-baselined communications, protocols, and protocol application values for certain ICS protocols in your environment. When Baselines are enabled, notifications will be produced for assets and behaviors that have not been added to your baseline. Use the Learning Mode feature to add assets and behaviors to your baseline before attempting to run baselines without Learning Mode. Refer to the Dragos User Guide for additional information on the Baseline feature.

Baselines Enabled

Include External Assets

Learning Mode ⓘ

Learning Mode puts the Platform into a state where all observed assets and behaviors are added to the baseline. Assets and behaviors are only added to the baseline when Baselines are enabled. Learning Mode should be used to build your baseline before enabling Baselines with Learning Mode disabled. It is recommended to enable New Sensor Learning Mode before additional sensors are connected to your Platform.

Learning Mode Enabled

Learning mode ends 02/12/24, 07:55 PM MST

Learning Mode for New Sensors Enabled

Enable Learning Mode for new sensors connected for 48 hours

Reset Baseline

This action will remove any data associated with the baseline settings in your environment. You will no longer have any assets, communications, or notification rules associated with a baseline. This action cannot be undone.

Figure 15. Related Assets for Baseline Monitoring on the Dragos Platform

In addition, CIP-010 requires verification that approved changes did not alter existing security controls. Entities could leverage the Dragos Platform as an additional detective control to review communications that occur outside of an established baseline. Asset-specific detail dashboards can provide information that may help identify unintended changes to a baseline. See Figures 16 and 17.

Achieving a constant level of CIP compliance across all facilities, applicable Cyber Assets, and requirements with zero deficiencies throughout an audit period is difficult. Attempting to run a CIP program effectively without the integration of security and compliance solutions is impossible. Because each solution that is added to a CIP program brings with it compliance burdens and risk, it is important to pursue a balance between security and compliance. When a solution like the Dragos Platform can be leveraged across numerous standards and requirements, and integrate with numerous other security and compliance tools (see Figure 18), then it should be given special consideration due to the broad benefits provided.

## INSM and FERC Order 893

As entities consider OT network visibility solutions, they can consult this paper to identify the necessary evaluations to ensure a solution that will satisfy existing requirements as well as perform the desired features for security and compliance. Organizations always need to be looking forward as well and should consider monitoring and contributing to the INSM and CIP-015 Standards development process. On April 30, 2024, the CIP-015 Standard passed industry balloting approval and will move forward through the remainder of the regulatory process seeking FERC approval and rulemaking. The original FERC Order emphasizes the importance of including INSM requirements in the future NERC Standard by stating:

***Including INSM requirements in the CIP Reliability Standards would ensure that responsible entities maintain visibility over communications between networked devices within a trust zone (i.e., within an ESP), not simply monitor communications at the network perimeter access point(s), i.e., at the boundary of an ESP as required by the current CIP requirements. Entities could leverage the Dragos Platform to meet the forthcoming INSM requirements under NERC CIP-015. The Dragos Platform provides comprehensive network security monitoring within a CIP-networked environment for High and Medium impact BES Cyber Systems and comprehensive threat detection to detect anomalous behavior and malicious activity. By deploying the Dragos Platform, entities can monitor within trust zones and gain robust analysis capabilities with case management, expert-authored playbooks for response, and comprehensive reporting capabilities.***

This expanding requirement and capability will be required in the future, and the associated projects and timeline to implement may be impactful to entities. In an effort to encourage organizations to pursue these projects before they are mandatory, FERC Order 893 has provided incentives for prequalified cybersecurity projects including INSM. As entities await the INSM requirements and implementation dates, they can also pursue early project activities with incentives allowed under Order 893.

## Going Beyond Compliance

Although it may not feel like it to most entities that are subject to the NERC CIP Standards, the standards were developed as a minimum set of security requirements designed to ensure the reliability of the BES. Many entities frequently implement security controls in one area or another that exceed the specifics of a requirement—and they gain the security benefits of the additional capabilities. Many of these controls are preventative or detective, but there are also some extremely important security capabilities of the Dragos Platform specific to incident response and information sharing that entities should pursue.

The CIP-008 Incident Reporting and Response Planning Standard provides specific requirements in relation to processes and plans necessary for incident identification, required elements of a response plan, incident handling procedures, plan testing, notification requirements, and programmatic reviews.

These are all important and necessary elements of an effective incident response capability for an entity. Remember, though, that entities can fall prey to a false sense of security when they aim for compliance with only the minimum requirements. Having plans and procedures for “an attack” may not adequately capture the wide variety of attack scenarios that could occur. Having specific response approaches developed for various scenarios may be far more effective.

As shown in Figure 19, the Dragos Platform provides for specific playbook-driven responses based on identified detections. Although this is not required for compliance, it provides a more predictable, calm, and guided approach to response activities when there may be high levels of chaos during a real-world incident.

One of the more interesting capabilities of the Dragos Platform is the Neighborhood Keeper<sup>10</sup> program (see Figure 20). We mention it now because, although there are information sharing and notification requirements within CIP-008, the capabilities of Neighborhood Keeper go far beyond the compliance requirements. Neighborhood Keeper is a voluntary program that Dragos Platform customers can choose to participate in. An existing platform customer can deploy Dragos Sensors and SiteStore in their ICS/OT environments. Then if they choose to opt in, they can enroll in the Neighborhood Keeper program (see Figure 21).

Figure 19. Incident Response Playbook Capabilities of the Dragos Platform

Figure 20. Neighborhood Keeper Overview

Figure 21. Neighborhood Keeper Enrollment

<sup>10</sup> "Neighborhood Keeper: Collective Defense for Industrial Cybersecurity," [www.dragos.com/wp-content/uploads/relocated/n/Neighborhood\\_Keeper\\_Datasheet.pdf](http://www.dragos.com/wp-content/uploads/relocated/n/Neighborhood_Keeper_Datasheet.pdf)

If an entity voluntarily enrolls, there are no additional CIP requirements to participate. For example, if the Dragos Sensors and SiteStore are associated with CIP facilities, they would need to comply with CIP as applicable assets, as referenced earlier in this paper. If the Dragos Platform is being used to satisfy CIP compliance requirements, then it would already be configured and operated as mentioned in this paper based on the requirements for which it is being used. If an entity chooses to take the detection indicators and share that information with peers and the electric sector throughout North America, the only unique CIP concern that emerges is the question of whether the information being shared is BES CSI. The information protection approach taken within the Neighborhood Keeper program is one of the more powerful elements of this unique information sharing capability in that the customer-related data and potential BES CSI remain at the entity site. The only data shared is anonymized metadata that provides only details on the threat detection. No entity-specific data with any CIP-related context is shared.

This threat detection–driven anonymous alert is received by the Neighborhood Keeper participants, who can see information from across the community about what is happening based on a sector. They can see what vulnerabilities or adversary methods are being detected and then use that information to inform their internal efforts. Other program participants, such as government organizations and information sharing and analysis centers (ISACs), can gather insights from the detections to determine whether there is a coordinated attack across multiple participants or sectors. They can utilize the information to inform their actions across critical infrastructure organizations.

The last item to highlight with Neighborhood Keeper is the capability to operationalize Cyber Mutual Assistance requests for help by an anonymous participant. Other participants can respond and can then further connect (if appropriate) for additional assistance. Although none of this is required for compliance, all of the features of the Neighborhood Keeper program are what the ICS community of asset owners and operators need.

## Getting Married

As entities look for potential solutions to help them in their CIP programs, they are not looking for frequent or dramatic changes within their CIP environments. Entities do not want to try a solution, identify issues, and then try something different; nor do they want to select an emerging innovative company technology and then see that organization get acquired or drop a product line. Entities are looking for solutions that are sustainable and will have an extended, predictable product lifecycle that can sustain multiyear deployment programs across geographies. Entities are not looking to “date” CIP solution providers, they are looking to “settle down and marry” CIP solution providers. This paper outlined many of the criteria entities should explore as they make the decision about what solution provider to marry.

## Conclusion

As electric sector entities evaluate the Dragos Platform, they should consider four criteria in relation to selecting a monitoring and detection solution provider across their CIP facilities.

- **Is the solution provider company a good fit for doing business with CIP-affected entities?** Whereas many solution providers struggle to understand CIP and how it affects their products, Dragos truly has a focus area strength and subject matter expertise in electric sector operations, ICS environments, and NERC CIP.
- **Can the solution be configured and maintained in a compliant manner?** As discussed throughout this paper, no solution is automatically compliant—it must be capable of being configured in a compliant manner and then integrated into an entity's CIP program. The Dragos Platform V2.2 solution reviewed in this paper provides the necessary configuration capabilities for entities to pursue during deployment with Dragos support and throughout the lifecycle of the solution.
- **Does the selected solution perform the advertised functions to help with a given compliance requirement?** This paper provided examples and references to numerous NERC CIP Requirements where the Dragos Platform could be utilized by an entity to satisfy strict compliance with a requirement or as an additional security control within a CIP program.
- **Does the selected solution offer any additional capabilities beyond compliance that could help our business?** The Dragos Platform truly does bring additional detection, incident response, and information-sharing capabilities to an organization that go far beyond the compliance requirements. Its features help an entity with the dynamic challenges of providing a safe, reliable, and secure operational environment.

Adversary attacks will continue to evolve, and so, too, will regulation-based Cyber Security requirements such as the NERC CIP standards. Electric entities facing these challenges cannot face them alone. Instead, they need to pursue partners and solutions that fit with their operational needs and business objectives.
